## Doing

### 1 Introduction

### 2 Preliminaries

To start, let's solidify the notation used in this report.

We shall denote groups and sets with capital letters, like  $G$ ,  $H$ , and elements of those groups with lower case letters, like  $g$ ,  $h$ . Greek letters shall denote mappings, generally  $\phi$ ,  $\psi$ , etc. with  $\iota$  reserved for the identity map, and we will write mappings on the right.

We will use  $\mathbb{N}$  to denote the natural numbers (not including 0),  $\mathbb{Z}$  to denote the integers, and  $\mathbb{R}$  to denote the real numbers.

To denote the cyclic group of order  $n$  we will use  $C_n$ ,  $D_{2n}$  to denote the cyclic group of order  $2n$ ,  $A_n$  to denote the alternating group over  $n$  elements,  $S_n$  to denote the symmetric group over  $n$  elements, and  $Q_8$  to denote the quaternion group. The trivial group,  $\{1\}$  is denoted by  $\mathbf{1}$ .

Let's move on to review some facts and theorems which will be valuable later on, as well as introduce some new concepts and prove some new results!

**Definition 2.1.** A permutation of a set  $X$  is a bijection from  $X$  to  $X$ . The symmetric group  $X$  is the set of all permutations of  $X$  under composition. We write  $\text{Sym } X$  to denote this. It is easy to show  $\text{Sym } X$  is a group.

**Definition 2.2.** If  $G$  is a group, and  $H \subseteq G$ , then  $H$  is a subgroup of  $G$  if it is a group in its own right with the multiplication from  $G$ . We write  $H \leq G$  to mean  $H$  is a subgroup of  $G$ .

If  $H$  is closed under conjugation, i.e. for all  $g \in G$  and  $h \in H$ ,  $g^{-1}hg \in H$ , then we say  $H$  is a normal subgroup of  $G$ . We write  $H \trianglelefteq G$  to mean  $H$  is a normal subgroup of  $G$ .

**Definition 2.3.** If  $G$  is a group and  $X \subseteq G$ , then the subgroup generated by  $X$  is the intersection of all subgroups of  $G$  containing  $X$ . This is denoted  $\langle X \rangle$ . The proof that  $\langle X \rangle$  is a subgroup of  $G$  is omitted. The elements of  $X$  are called generators of  $G$ .

**Definition 2.4.** If  $G$  is a group with subgroup  $H$  then the right coset of  $H$  in  $G$  with representative  $g \in G$  is:

$$Hg = \{ hg \mid h \in H \}$$

**Definition 2.5.** The order of a group,  $G$ , is the number of elements in  $G$ , denoted  $|G|$ . The order of an element  $g \in G$  is the smallest  $i \in \mathbb{N}$  such that  $g^i = 1$ .

**Definition 2.6.** If  $G$  and  $H$  are groups with elements  $g_1, g_2 \in G$ , then a map:

$$\phi : G \rightarrow H$$

is a homomorphism if:

$$(g_1 g_2) \phi = (g_1 \phi)(g_2 \phi)$$

If  $\phi$  is bijective, then we call it an isomorphism, with  $G \cong H$  denoting that  $G$  is isomorphic to  $H$ . And if  $\phi$  is an isomorphism from  $G$  to itself, then we call it an automorphism of  $G$ .

**Lemma 2.7.** *The set of all automorphisms of a group  $G$  form a group under composition. Indeed, this is called the automorphism group of  $G$ , denoted  $\text{Aut } G$ .*

*Proof.* Let  $A = \text{Aut } G = \{ \phi : G \rightarrow G \mid \phi \text{ is an isomorphism} \}$ , and let  $\phi \in A$ . Denote an element of  $G$  by  $g$ .

We know already that the composition of two isomorphisms is an isomorphism, so  $A$  is closed under composition.

The identity map,  $\iota : g \mapsto g$ , is certainly an automorphism of  $G$  and so  $A \neq \emptyset$ .

Indeed,  $\iota : g \mapsto g$  is the identity of  $A$ , since:

$$g\phi\iota = (g\phi)\iota = g\phi \quad \text{and} \quad g\iota\phi = (g\iota)\phi = g\phi$$

And inverses clearly exists, because automorphisms are bijections, and bijections are invertible. Hence  $A = \text{Aut } G$  is a group.  $\square$

**Lemma 2.8.** *The automorphism group of  $C_n$  is isomorphic to the multiplicative group of integers mod  $n$ .*

$$\text{i.e. } \text{Aut } C_n \cong (\mathbb{Z}/n\mathbb{Z})^\times$$

*Proof.* Let  $C_n = \langle x \rangle$ . Any automorphism,  $\varphi$  of  $C_n$  has the property:

$$(x^i)\varphi = (x\varphi)^i$$

Hence  $\varphi$  is determined by it's effect on a generator,  $x$ , and preserves element order. In particular,  $\varphi$  sends generators to generators. So for  $\varphi$  to be an automorphism, it must send  $x$  to another generator, say  $x^k$ . An element  $x^k$  generates  $C_n$  if  $x^k$  has order  $n$ , i.e. when  $k$  and  $n$  are co-prime. Denote the automorphism sending  $x$  to  $x^k$  by  $\varphi_k$ .

Let's now investigate how these automorphisms behave. Let  $\varphi_k, \varphi_l \in \text{Aut } C_n$ , and consider:

$$x\varphi_k\varphi_l = (x^k)\varphi_l = (x^k)^l = x^{(kl)} = x\varphi_{kl} \pmod{n}$$

Because multiplication modulo  $n$  is commutative,  $x^{kl} = x^{lk}$ , so  $\text{Aut } C_n$  is abelian.

Now consider  $\theta : \text{Aut } C_n \rightarrow (\mathbb{Z}/n\mathbb{Z})^\times$  defined by  $\varphi_k\theta = k$ . We will show  $\theta$  is an isomorphism. Every  $k \in (\mathbb{Z}/n\mathbb{Z})^\times$  is co-prime to  $n$  and so  $x^k$  is a generator of  $C_n$ , hence there is some  $\varphi_k \in \text{Aut } C_n$  such that  $\varphi_k\theta = k$ . So  $\theta$  is surjective. If  $\varphi_k\theta = \varphi_l\theta$  then  $k = l$ , so  $\theta$  is also injective. Finally,  $\theta$  is a homomorphism because:

$$(\varphi_k\varphi_l)\theta = \varphi_{kl}\theta = kl = (\varphi_k\theta)(\varphi_l\theta)$$

So  $\theta : \text{Aut } C_n \rightarrow (\mathbb{Z}/n\mathbb{Z})^\times$  is an isomorphism.  $\square$

This collection of theorems is extremely useful for describing group structures. Hopefully these ring some bells. We will use them without proof.

**Theorem 2.9** (Lagrange's Theorem for Finite Groups). *Let  $G$  be a finite group with subgroup  $H$ . Then  $|H|$  divides  $|G|$ . In particular, the order of an element of  $G$  must divide  $|G|$ .*

For the Sylow Theorems, let  $G$  be a group of order  $p^n m$  where  $p$  is a prime and  $p \nmid m$ .

**Theorem 2.10** (1<sup>st</sup> Sylow Theorem).  *$G$  has a Sylow  $p$ -subgroup, i.e. a subgroup of order  $p^n$ .*

**Theorem 2.11** (2<sup>nd</sup> Sylow Theorem). *All Sylow  $p$ -subgroups of  $G$  are conjugate to each other. In particular, if  $G$  has a unique Sylow  $p$ -subgroup, then it is a normal subgroup.*

**Theorem 2.12** (3<sup>rd</sup> Sylow Theorem). *Let  $n_p$  denote the number of Sylow  $p$ -subgroups of  $G$ . Then:*

$$(i) \quad n_p \mid m$$

$$(ii) \quad n_p \equiv 1 \pmod{p}$$

**Theorem 2.13** (1<sup>st</sup> Isomorphism Theorem). For groups  $G$  and  $H$ , and a homomorphism  $\psi : G \rightarrow H$ :

$$G / \ker \psi \cong \text{im } \psi$$

**Theorem 2.14** (2<sup>nd</sup> Isomorphism Theorem). Let  $G$  be a group, with subgroup  $H$  and normal subgroup  $N$ . Then:

- (i)  $H \cap N$  is a normal subgroup of  $G$
- (ii)  $HN$  is a subgroup of  $G$
- (iii)  $H/(H \cap N) \cong (HN)/N$

**Theorem 2.15** (3<sup>rd</sup> Isomorphism Theorem). Let  $G$  be a group, with normal subgroups  $H$  and  $N$ , such that  $H \leq N \leq G$ . Then:

- (i)  $(N/H)$  is a normal subgroup of  $G/H$
- (ii)  $(G/H)/(N/H) \cong (G/H)$

## 2.1 Semidirect Product

We already know about the direct product:

**Definition 2.16** (Direct Product). For groups  $N$  and  $H$ , the direct product,  $G = N \times H$  is a group of ordered pairs of elements  $(n, h)$  where  $n \in N$  and  $h \in H$  with the operation:

$$(n_1, h_1)(n_2, h_2) = (n_1 n_2, h_1 h_2)$$

Moreover, if  $\bar{N} = N \times \mathbf{1}$  and  $\bar{H} = \mathbf{1} \times H$ , then:

- (i)  $\bar{N} \trianglelefteq G$  and  $\bar{H} \trianglelefteq G$
- (ii)  $\bar{N} \cap \bar{H} = \mathbf{1}$
- (iii)  $\bar{N}\bar{H} = \{nh \mid n \in N, h \in H\} = G$

Now let's seek a slightly more general way to combine groups, by relaxing that  $H$  must be normal. So we have:

$$N \trianglelefteq G, H \leq G, NH = G, \quad \text{and} \quad N \cap H = \mathbf{1}$$

Consider the set, (not the direct product):

$$N \times H = \{ (n, h) \mid n \in N, h \in H \}$$

and a map

$$\phi : N \times H \rightarrow G \quad \text{defined by} \quad (n, h) \mapsto nh$$

We want  $\phi$  to be an isomorphism.

To show  $\phi$  is injective, take  $n_1, n_2 \in N$  and  $h_1, h_2 \in H$ , and assume  $n_1 h_1 = n_2 h_2$ . Then multiplying on the left by  $n_2^{-1}$  and on the right by  $h_1^{-1}$  gives:

$$n_2^{-1} n_1 = h_2 h_1^{-1}$$

On the left we have an element of  $N$  and on the right, an element of  $H$ , so  $n_2^{-1} n_1 = h_2 h_1^{-1} \in N \cap H$ . But  $N \cap H = \mathbf{1}$  so then  $n_2^{-1} n_1 = h_2 h_1^{-1} = 1$ . Hence:

$$n_1 = n_2 \quad \text{and} \quad h_1 = h_2$$

To show  $\phi$  is surjective, consider the image,  $\text{im } \phi = \{nh \mid n \in N, h \in H\}$ . This is by definition  $NH = G$ , so  $\phi$  is surjective, and hence a bijection.

For  $\phi$  to be a homomorphism, we need:

$$\begin{aligned} [(n_1, h_1)(n_2, h_2)]\phi &= (n_1, h_1)\phi(n_2, h_2)\phi \\ &= n_1h_1n_2h_2 \\ &= n_1h_1n_2h_1^{-1}h_1h_2 \\ &= (n_1h_1n_2h_1^{-1})(h_1h_2) \end{aligned}$$

But  $N$  is normal in  $G$  so  $h_1n_2h_1^{-1}$  is just another element in  $N$ , say  $n_3$ . So:

$$[(n_1, h_1)(n_2, h_2)]\phi = (n_1n_3)(h_1h_2) = (n_1n_3, h_1h_2)\phi$$

We know that  $\phi$  is injective, so then:

$$(n_1, h_1)(n_2, h_2) = (n_1n_3, h_1h_2)$$

This tells us the multiplication that will make  $NH$  a group. Because  $N \trianglelefteq G$ , the map

$$\varphi_{h_1} : n_2 \mapsto h_1n_2h_1^{-1} = n_3$$

is an automorphism of  $N$ . This gives rise to the definition:

**Definition 2.17** (Semidirect Product).

- (i) For a group  $G$  with normal subgroup  $N$  and subgroup  $H$  with  $NH = G$  and  $N \cap H = \mathbf{1}$ ,  $G$  is the internal semidirect product of  $N$  by  $H$ , written  $G = N \rtimes H$ .
- (ii) For groups  $N$  and  $H$ , and a homomorphism  $\psi : H \rightarrow \text{Aut } N$ , the external semidirect product of  $N$  by  $H$  via  $\psi$  is the set:

$$N \rtimes H = \{ (n, h) \mid n \in N, h \in H \}$$

with multiplication:

$$(n_1, h_1)(n_2, h_2) = (n_1(n_2\phi_{h_1}), h_1h_2)$$

denoted:

$$N \rtimes_{\psi} H$$

**Lemma 2.18.** For a group  $G$  with  $N \leq G$  and  $H \leq G$ , with  $N \cap H = \mathbf{1}$  then:

$$|NH| = |\{nh \mid n \in N, h \in H\}| = |N| \cdot |H|$$

*Proof.* We just saw above that for elements  $n \in N$  and  $h \in H$ , the map:

$$\phi : N \times H \rightarrow NH \quad \text{defined by} \quad (n, h) \mapsto nh$$

is a bijection. The result follows immediately from this. □

## 2.2 Group Actions

Some snazzy introduction.

**Definition 2.19.** Let  $G$  be a group, and  $\Omega$  be a set, with elements  $g \in G$  and  $\omega \in \Omega$ . Consider a map  $\mu : \Omega \times G \rightarrow \Omega$ , and write  $\omega^g$  for the image of  $(\omega, g)$  under  $\mu$ . So we have:

$$\mu : \Omega \times G \rightarrow \Omega \quad \text{defined by} \quad (\omega, g) \mapsto \omega^g$$

We say  $G$  acts on  $\Omega$  if for all  $g_1, g_2 \in G$  and all  $\omega \in \Omega$ :

$$(i) \quad (\omega^{g_1})^{g_2} = \omega^{(g_1 g_2)}$$

$$(ii) \quad \omega^1 = \omega$$

We call  $\mu$  the group action of  $G$  on  $\Omega$ .

This might remind you of a homomorphism. Indeed we have a result:

**Lemma 2.20.** *A group action induces a homomorphism. Specifically, let  $G$  be a group which acts on a set  $\Omega$ , with  $g \in G$  and  $\omega \in \Omega$ , and define:*

$$\rho_g : \Omega \rightarrow \Omega \quad \text{by} \quad \omega \mapsto \omega^g$$

Then:

$$\rho : G \rightarrow \text{Sym } \Omega \quad \text{defined by} \quad g \mapsto \rho_g$$

is a homomorphism.

*Proof.* Firstly,  $\rho_g$  is indeed a permutation of  $\Omega$  because it is invertible (and therefore a bijection), with:

$$(\rho_g)^{-1} = \rho_{g^{-1}}$$

Consider  $g, h \in G$  and their corresponding maps,  $\rho_g, \rho_h \in \text{Sym } \Omega$ . Then:

$$\omega(g\rho)(h\rho) = \omega\rho_g\rho_h = (\omega^g)^h = \omega^{(gh)} = \omega\rho_{gh} = \omega(gh)\rho$$

Thus  $\rho$  is a homomorphism. □

A group acting on the set its cosets will be very useful:

**Definition 2.21.** For a group  $G$  with  $H \leq G$ , let  $\Omega = \{Hg \mid g \in G\}$ , i.e. the set of cosets of  $H$  in  $G$ . If  $x \in G$ , define a group action:

$$\Omega \times G \rightarrow \Omega \quad \text{by} \quad (Hg, x) \mapsto Hgx$$

**Lemma 2.22.** *The action above is well defined, meaning the action is independent of our choice of representative  $g$ .*

*Proof.* □

### 3 First Classifications

Let's start with the easiest case: groups of order 1. Any group  $G$  must have an identity element, and so that's all our possible elements used up! All groups of order 1 are isomorphic to the trivial group,  $\mathbf{1}$ .

What about groups of prime order? Let  $G$  be a group of order  $p$ , where  $p$  is a prime number. Then Lagrange's Theorem tell us all elements must have order 1 or  $p$ . Pick some  $x \in G$  with  $x$  having order  $p$ . Then  $\langle x \rangle = G$  so  $G$  is cyclic and  $G \cong C_p$ .

## 4 Groups of Order $pq$

Let  $G$  be a group of order  $pq$  where  $p, q$  are prime numbers with  $p > q$ , and let  $n_p$  and  $n_q$  denote the number of Sylow  $p$ -subgroups and Sylow  $q$ -subgroups of  $G$  respectively. Then by Theorem 2.12:

$$n_p \equiv 1 \pmod{p} \quad \text{and} \quad n_p \mid q \implies n_p = 1$$

$$n_q \equiv 1 \pmod{q} \implies n_q = 1, q + 1, 2q + 1, \dots \quad \text{and} \quad n_q \mid p$$

So  $G$  has a unique Sylow  $p$ -subgroup, say  $P \trianglelefteq G$ , and a Sylow  $q$ -subgroup,  $Q \leq G$ . Because  $p$  and  $q$  are prime numbers,  $P \cong C_p$  and  $Q \cong C_q$ . Pick generators for each, say  $\langle x \rangle = P$  and  $\langle y \rangle = Q$ . We have 2 possibilities for  $n_q$ :  $p - 1$  is a multiple of  $q$  or 1.

**Case 1:**  $q \nmid p - 1$ .

If  $p - 1$  is not a multiple of  $q$  then  $n_q = 1$  and  $Q \trianglelefteq G$ , hence:

$$G = P \times Q \cong C_{pq}$$

**Case 2:**  $q \mid p - 1$ .

If  $p - 1$  is a multiple of  $q$  then  $n_q = p$  and so  $Q$  is not normal in  $G$ . By Lagrange's Theorem,  $P \cap Q = \mathbf{1}$  and by Lemma 2.18,  $|PQ| = pq$ . Hence, as well as the direct product, we have  $G = P \rtimes Q$ , some non-trivial semidirect product.

By Lemma 2.8,  $\text{Aut } C_p \cong (\mathbb{Z}/p\mathbb{Z})^\times \cong C_{p-1}$ . So if  $\nu \in (\mathbb{Z}/p\mathbb{Z})^\times$ , then  $x \mapsto x^\nu$  is an automorphism. We know also that  $C_{p-1}$  has a unique subgroup of order  $q$ , hence  $G$  has the presentation:

$$G = \langle x, y \mid x^p = y^q = 1, y^{-1}xy = x^a \rangle$$

where  $a$  is a generator for the subgroup of order  $q$  in  $(\mathbb{Z}/p\mathbb{Z})^\times$ .

Notice that picking different generators are equivalent up to isomorphism because the composition of two isomorphisms is an isomorphism.

So any group of order  $pq$  is isomorphic to either:

$$\begin{array}{ll} C_{pq} & \text{or} \quad \langle x, y \mid x^p = y^q = 1, y^{-1}xy = x^a \rangle \quad \text{if } q \mid p - 1 \\ & C_{pq} \quad \text{if } q \nmid p - 1 \end{array}$$

### 4.1 Groups of Order $2p$

To illustrate an example of groups of order  $pq$ , let's take  $q = 2$ . Because every prime greater than 2 is odd,  $p - 2$  is an even number, and so  $2 \mid p - 1$ .

An element  $\alpha \in (\mathbb{Z}/p\mathbb{Z})^\times$  of order 2 satisfies  $\alpha^2 = 1$ , hence  $\alpha = 1$  or  $-1$ . But 1 has order 1, so  $\alpha$  can only be  $-1$ . Side-note: from the proof of Lemma 2.8, this corresponds to the inverse map  $\beta : x \mapsto x^{-1}$ .

So, in addition to  $C_{2p}$ , we have:

$$G \cong \langle x, y \mid x^p = y^2 = 1, y^{-1}xy = x^{-1} \rangle$$

Which is the presentation for the dihedral group of order  $2p$ ,  $D_{2p}$ .

Hence a group of order  $2p$  is isomorphic to one of:

$$C_{2p} \quad \text{or} \quad D_{2p}$$

## 5 Groups of Order $p^2$

Let  $G$  be a group of order  $p^2$ . First, we will prove a useful lemma:

**Lemma 5.1.** *If  $G$  is a  $p$ -group (i.e. a group of prime power order), then every subgroup of index  $p$  is normal.*

*Proof.* Let  $H$  be a subgroup of  $G$ , with index  $p$ . We know kernels are normal subgroups, so we will show that  $H$  is the kernel of some homomorphism. Let  $\Omega$  be the set of all cosets of  $H$ . So by definition,  $|\Omega| = p$ . By Lemma 2.20, there is a homomorphism:

$$\rho : G \rightarrow S_p$$

Let's investigate the kernel of  $\rho$ . If we have  $x \in \ker \rho$ , then:

$$(H1)x = H1 = H$$

which means  $x \in H$ . So the kernel of  $\rho$  is  $H$ . Hence,  $H \trianglelefteq G$ . □

By Lagrange's Theorem, the elements of  $G$  have order 1,  $p$  or  $p^2$ .

If  $x \in G$  has order  $p^2$ , then  $x$  generates  $G$  so  $G \cong C_{p^2}$ .

If  $G$  does not have an element of order  $p^2$  then all elements, except the identity, have order  $p$ . We know that  $G$  must have a subgroup of order  $p$ ,  $P$ , and because  $p$  is prime,  $P \cong C_p$ . Pick a generator for  $P$ , say  $x$  and an element  $y \in G$  such that  $y \notin P$ . Then  $y \neq x^i$  for any  $i$ .

If  $y^j = x^i$  for some  $i$  and  $j$ , then:

$$(y^j)^{1-j} = (x^i)^{1-j} = y^{j-j+1} = y = x^{i(1-j)} = x^k \quad \text{for some } k, \text{ a contradiction.}$$

So no power of  $y$  is equal to any power of  $x$ . Because  $y$  has order  $p$ , it generates a subgroup of order  $p$ ,  $\bar{P}$ , with  $P \cap \bar{P} = \mathbf{1}$ . The lemma tells us that both  $P$  and  $\bar{P}$  are normal, and by Lemma 2.18,  $|P\bar{P}| = p^2 = |G|$ , so:

$$G = P \times \bar{P} \cong C_p \times C_p$$

If  $G$  has no elements of order  $p$  or  $p^2$ , then it only has elements of order 1, which is the trivial group.

Hence any group of order  $p^2$  is isomorphic to one of:

$$C_{p^2} \quad \text{or} \quad C_p \times C_p$$

## 6 Groups of order 12

We will see later, that we need groups of order 12 as a special case for groups of order  $p^2q$  for prime numbers  $p$  and  $q$ .

Let  $G$  be a group of order  $12 = 2^2 \cdot 3$ , and  $n_3$  and  $n_2$  denote the number of Sylow 3-subgroups and Sylow 2-subgroups of  $G$  respectively. By Theorem 2.12:

$$n_2 \equiv 1 \pmod{2} \text{ and } n_2 \mid 3 \implies n_2 = 1$$

$$n_3 \equiv 1 \pmod{3} \text{ and } n_3 \mid 4 \implies n_3 = 1 \text{ or } 4$$

So  $G$  has a unique Sylow 2-subgroup of order 4, say  $H \trianglelefteq G$ , and we have already classified groups of order 4, so  $H$  is isomorphic to either  $V_4$  (the Klein 4 group) or  $C_4$ . A Sylow 3-subgroup,  $K \leq G$  will have order 3, so  $K \cong C_3$ . Say  $K = \langle x \rangle$ .

Lagrange's Theorem tells us  $H$  has elements of order 1, 2, and 4, and  $K$  has elements of order 1 and 3. Hence  $H \cap K = \mathbf{1}$ . Lemma 2.18 tells us:

$$|HK| = |H| \cdot |K| = 12$$

Hence  $G = HK$ ,  $H \trianglelefteq G$ , and  $H \cap K = \mathbf{1}$ . If we consider groups with 4 Sylow 3-subgroups then we can conclude that they are some semidirect product,  $G = H \rtimes K$ .

Since an automorphism,  $\varphi$ , must map generators to generators,  $\text{Aut } C_4 \cong C_2$  because  $C_4$  has two generators. An automorphism of  $V_4$  corresponds to a permutation of the three non-identity elements, hence  $\text{Aut } V_4 \cong S_3$ .

**Case 1:**  $H \cong C_4$  i.e.  $G \cong C_4 \rtimes C_3$ .

Let  $H = \langle y \rangle$ .

A homomorphism  $\psi : K \rightarrow \text{Aut } H \cong C_2$ , preserves order and together with Lagrange's Theorem means that the only possibility for  $\psi$  is trivial, i.e.  $K\psi = \mathbf{1}$ .

Hence  $G \cong C_4 \times C_3 \cong C_{12}$ .

**Case 2:**  $H \cong V_4$  i.e.  $G \cong (C_2 \times C_2) \rtimes C_3$ .

Let  $H = \langle y, z \rangle$ .

A trivial homomorphism  $K\psi = \mathbf{1}$  yields the direct product. What non-trivial homomorphisms are there? The automorphism group,  $\text{Aut } H \cong S_3$  is of order 6, and so has a unique subgroup of order 3, by Theorem 2.12. We know already that a homomorphism  $\psi : K \rightarrow \text{Aut } H$  is determined by where it sends the generator  $x$ , so for  $\psi$  to be non-trivial, it must send  $x$  to an element of order 3 in  $\text{Aut } H$ .

There are 2 such elements. Because  $\text{Aut } H \cong S_3$ , we will think of them as the permutations of order 3 of the set  $\{1, 2, 3\}$ . Denote them  $a = (1\ 2\ 3)$  and  $b = (1\ 3\ 2)$ . Notice that  $b = a^{-1}$ , so we have homomorphisms:

$$\psi_1 : x \mapsto a \quad \text{and} \quad \psi_2 : x \mapsto a^{-1}$$

It appears we have 2 choices, but this is not the case. If we define  $\theta : K \rightarrow K$  by  $x\theta = x^{-1}$  then  $\theta\psi_1 = \psi_2$ . And notice that  $\theta$  is an automorphism of  $K$ , so the semidirect products with  $\psi_1$  and  $\psi_2$  are isomorphic. Hence (up to isomorphism) there is one non-trivial homomorphism  $\psi : K \rightarrow \text{Aut } H$ . So  $x \in K$  acts by permuting the 3 non-identity elements of  $H$ .

We will show that in this case,  $G \cong A_4$ . First, let's check  $A_4$  has the same subgroup structure as  $G$ . There is a subgroup isomorphic to  $C_3$  in  $A_4$ , generated by the 3-cycle  $(1\ 2\ 3)$ :

$$\bar{K} = \langle (1\ 2\ 3) \rangle$$

We can also find a subgroup isomorphic to  $V_4$ :

$$\bar{H} = \{1, (1\ 2)(3\ 4), (1\ 3)(2\ 4), (1\ 4)(2\ 3)\}$$

Indeed, we can check that  $\bar{H}$  is normal in  $A_4$ . We can see that  $\bar{H} \cap \bar{K} = \mathbf{1}$  because  $\bar{H}$  contains no 3-cycles, and that  $\bar{H}\bar{K} = A_4$ . So we can conclude that  $A_4 = \bar{H} \rtimes \bar{K}$ .

Let's investigate how If we let  $\alpha = (1\ 2)(3\ 4)$ ,  $\beta = (1\ 4)(2\ 3)$  and  $\gamma = (1\ 2\ 3)$ , then we can write an element of  $A_4$  as  $\alpha^i \beta^j \gamma^k$  for some  $i, j$  and  $k$ . Define  $\phi : A_4 \rightarrow G$  by  $\phi : \alpha^i \beta^j \gamma^k \mapsto x^i y^j z^k$ . Then:

$$\beta\phi = (\gamma^{-1}\alpha\gamma)\phi = c^{-1}ac = b$$

So conjugation acts in the same way. Hence we can conclude that  $G \cong A_4$ .

If we instead consider  $G$  where  $K \trianglelefteq G$ , i.e.  $G = K \rtimes H$ , then we again have two cases:

**Case 1:**  $H \cong C_4$  i.e.  $G \cong C_3 \rtimes C_4$ .

Let  $H = \langle y \rangle$ .

We know  $\text{Aut } C_3 \cong C_2$  so a homomorphism  $\psi$  maps  $H$  to the trivial group or to  $\langle \beta : x \mapsto x^{-1} \rangle$ .

If  $H\psi = \mathbf{1}$  then  $G = K \times H \cong C_4 \times C_3$ , which we have already seen.

If  $H\psi = \langle \beta \rangle$  then we have:

$$G = \langle x, y \mid x^3 = y^4 = 1, y^{-1}xy = x^{-1} \rangle$$

Now let  $a = xy^2$ . And remember,  $y^{-1}xy = x^{-1}$  means  $x$  commutes with  $y^2$ . So now:

$$a^3 = xy^2xy^2xy^2 = x^3y^6 = y^2$$

and

$$b^{-1}ab = y^{-1}xy^2y = (y^{-1}xy)y^2 = x^{-1}y^2 = y^2x^{-1} = a^{-1}$$

So:

$$G = \langle a, b \mid a^6 = 1, a^3 = b^2, b^{-1}ab = a^{-1} \rangle$$

This is known as the binary dihedral or dicyclic group, denoted  $\text{Dic}_{12}$ .

**Case 2:**  $H \cong V_4$  i.e.  $G \cong C_3 \rtimes (C_2 \times C_2)$ .

Let  $H = \langle y, z \rangle$ .

If  $\psi : H \rightarrow \text{Aut } K$  is trivial then we obtain the direct product again.

The image of a non-trivial homomorphism  $\psi : H \rightarrow \text{Aut } K$  is isomorphic to  $C_2$ , so by Theorem 2.13:  $\ker \psi \cong C_2$ .

We can choose  $\psi$  such that  $y\psi = \beta : x \mapsto x^{-1}$  and  $z\psi = \iota : x \mapsto x$ . Then:

$$G = \langle x, y, z \mid x^3 = y^2 = z^2 = 1, yz = zy, y^{-1}xy = x^{-1}, z^{-1}xz = x \rangle$$

Let  $a = xz$ . The order of  $a = \text{lcm}(\text{o}(x), \text{o}(z)) = \text{lcm}(2, 3) = 6$  because  $x$  and  $z$  commute.

So:

$$a^3 = x^3z^3 = z$$

and

$$y^{-1}ay = y^{-1}xzy = y^{-1}xyz = x^{-1}z = x^2z = a^2a^3 = a^{-1}$$

Hence:

$$G = \langle y, a \mid a^6 = y^2 = 1, a^{-1}ay = a^{-1} \rangle \cong D_{12}$$

So a group  $G$  of order 12 is isomorphic to one of:

$$C_{12}, \quad C_2 \times C_6, \quad A_4, \quad D_{12}, \quad \text{or} \quad \text{Dic}_{12}$$

## 7 Groups of Order $p^2q$

Let  $p$  and  $q$  be distinct prime numbers, and  $G$  be a group of order  $p^2q$ . We shall consider the cases  $p < q$  and  $p > q$  separately.

## 7.1 $p < q$

Let  $p < q$ , and let  $n_q$  denote the number of Sylow  $q$ -subgroups. Then by Theorem 2.12:

$$n_q \mid p^2$$

so  $n_q$  could be 1,  $p$  or  $p^2$ . Also:

$$n_q \equiv 1 \pmod{q}$$

If  $n_q = p$  then  $p$  must be congruent to 1 mod  $q$ , which is a contradiction since  $p < q$ . If  $n_q = p^2$  then we must have:

$$q \mid (p^2 - 1)$$

Factorising gives:

$$q \mid (p + 1)(p - 1)$$

So either:

$$q \mid (p + 1) \quad \text{or} \quad q \mid (p - 1) \quad \text{or both}$$

However,  $q$  cannot divide  $p - 1$  because  $p < q$  so  $q$  must divide  $p + 1$ . This is only the case when  $p = 2$  and  $q = 3$ , so  $|G| = 12$  which we have already classified.

Hence if  $|G| = p^2q \neq 12$  with  $p < q$ , then  $G$  possesses a unique Sylow  $q$ -subgroup,  $Q \cong C_q$ , which is normal in  $G$ . A Sylow  $p$ -subgroup,  $P \leq G$ , will have order  $p^2$  and by Lagrange's Theorem, intersects trivially with  $Q$ . And by applying Lemma 2.18:

$$|PQ| = |P| \cdot |Q| = p^2q$$

So we can conclude that  $G = Q \rtimes P$ .

We know, by Lemma 2.8, that  $\text{Aut } Q \cong (\mathbb{Z}/q\mathbb{Z})^\times$ , and we want a homomorphism,  $\psi : P \rightarrow \text{Aut } Q$ . We have two possibilities for a group of order  $p^2$ :

**Case 1:**  $P \cong C_{p^2}$  i.e.  $G \cong C_q \rtimes C_{p^2}$ .

Element order is preserved by  $\psi$  so let's consider what possibilities we have. Elements in  $P$  have order 1,  $p$  and  $p^2$ . Lagrange's Theorem tell us that  $\text{Aut } Q$  will have elements of order  $p$  if  $p \mid q - 1$ , and  $p^2$  if  $p^2 \mid q - 1$ . Notice that if  $p \mid q - 1$  then so will  $p^2$ .

Expecting 2 non-trivial semidirect products, one with trivial centre requiring  $p^2 \mid q - 1$ , and one with centre of order  $p$  requiring  $p \mid q - 1$ .

**Case 2:**  $P \cong C_p \times C_p$  i.e.  $G \cong C_q \rtimes (C_p \times C_p)$ .

This time,  $P$  only has elements of order 1 and  $p$ . If  $p \nmid q - 1$  then the only possibility is the trivial homomorphism and we recover the direct product again. So we can assume that  $p \mid q - 1$ .

Expecting only one semidirect product.

## 7.2 $p > q$

Let  $p > q$ , and let  $n_p$  denote the number of Sylow  $p$ -subgroups. Then by Theorem 2.12:

$$n_p \mid q$$

so  $n_p$  could be 1 or  $q$ . Also:

$$n_p \equiv 1 \pmod{p}$$

and because  $p > q$ , this forces  $n_p = 1$ . Hence  $G$  has a unique Sylow  $p$ -subgroup,  $P$ , of order  $p^2$ , and  $P \trianglelefteq G$ . A Sylow  $q$ -subgroup of  $G$ ,  $Q$ , will have order  $q$ , and so will be isomorphic to  $C_q$ . So by Lagrange's Theorem,  $P \cap Q = \mathbf{1}$ . Lemma 2.18 gives us that:

$$|PQ| = p^2q$$

Hence,  $G = P \rtimes Q$ .

For this report, we will narrow our focus to groups of order less than 31, i.e.  $p \leq 3$  and  $q \leq 7$ .

## 8 Groups of Order 24

Let  $G$  be a group of order 24, and let  $H$  be a Sylow 3-subgroup of  $G$ , so  $H \cong C_3$ . Let  $T$  be a Sylow 2-subgroup of  $G$ , so  $T$  has order 8. By Lagrange's Theorem,  $H \cap T = \mathbf{1}$  and then applying Lemma 2.18,  $|HT| = 24$ . Now let  $n_3$  denote the number of Sylow 3-subgroups, and by Theorem 2.12:

$$n_3 \equiv 1 \pmod{3} \quad \text{and} \quad n_3 \mid 8$$

Hence  $n_3$  is either 1 or 4.

If  $n_3 = 1$ , then  $H$  is normal in  $G$ . Thus  $G = H \rtimes T$ . We'll want a homomorphism  $\psi : \text{Aut } T \rightarrow H$ . From our classification of groups of order 8, we have 5 possibilities:

**Case 1:**  $T \cong C_8$  i.e.  $G \cong C_3 \rtimes C_8$

1 group

**Case 2:**  $T \cong (C_4 \times C_2)$  i.e.  $G \cong C_3 \rtimes (C_4 \times C_2)$

2 groups

**Case 3:**  $T \cong (C_2 \times C_2 \times C_2)$  i.e.  $G \cong C_3 \rtimes (C_2 \times C_2 \times C_2)$

1 group

**Case 4:**  $T \cong D_8$  i.e.  $G \cong C_3 \rtimes D_8$

2 groups

**Case 5:**  $T \cong Q_8$  i.e.  $G \cong C_3 \rtimes Q_8$

1 group — binary dihedral

If  $n_3 = 4$  then  $H$  is not normal. Now let  $G$  act by conjugation on the set of its Sylow 3-subgroups,  $\Omega = \{ H \mid H \text{ is a Sylow 3-subgroup of } G \}$ :

$$H^x = x^{-1}Hx = \{ x^{-1}hx \mid h \in H \} \quad \text{for } x \in G$$

This is indeed a group action because for  $x, y \in G$ :

$$(H^x)^y = (x^{-1}Hx)^y = (y^{-1}x^{-1})H(xy) = (xy)^{-1}H(xy) = H^{(xy)}$$

and:

$$H^1 = 1^{-1}H1 = H$$

Hence we obtain a homomorphism  $\rho : G \rightarrow S_4$ . The kernel of  $\rho$  must have order dividing  $\frac{|G|}{|\Omega|} = 6$  so can be either 1, 2, 3 or 6. CHECK!

The kernel cannot be of order 3, because  $G$  has no normal subgroup of order 3 (because kernels of homomorphism are normal in the domain group). Likewise the kernel cannot be of order 6 because every group of order 6 has a normal subgroup of order 3, which would be normal in  $G$  as well. Hence the kernel must have order 1 or 2.

If the kernel is of order 1, then  $\rho$  is actually an isomorphism, so  $G \cong S_4$ .

If the kernel is of order 2, then the image must be a subgroup of order 12, with no normal subgroup of order 3. Looking at our classification of groups of order 12, this must be isomorphic to  $A_4$ . We know that  $A_4$  has a normal subgroup of order 4, and so by the Correspondence Theorem,  $G$  must contain a normal subgroup of order 8, say  $T$ . By Lagrange's Theorem and Lemma 2.18, we can conclude that  $G = T \rtimes H$ . Again, we have 5 cases, but this time we'll exclude the trivial homomorphism, because that will just give us the direct product which we have already seen:

**Case 1:**  $T \cong C_8$  i.e.  $G \cong C_8 \rtimes C_3$

An automorphism of  $T$ ,  $\varphi$ , maps generators to generators, so say  $\langle x \rangle = T$ . Then  $x\varphi$  could be  $x, x^3, x^5$  or  $x^7$ . Notice that each of these, apart from  $\varphi : x \mapsto x$ , has order 2. Hence, and Lagrange's Theorem tells us that there are no non-trivial homomorphisms  $\psi : H \rightarrow \text{Aut } T$ . As a bonus:  $\text{Aut } C_8 \cong V_4$ .

**Case 2:**  $T \cong (C_4 \times C_2)$  i.e.  $G \cong (C_4 \times C_2) \rtimes C_3$

An automorphism of  $T$ ,  $\psi$  preserves element order, so if  $\langle x, y \mid x^4 = y^2 = 1, xy = yx \rangle = T$ , then  $x\psi$  must be of order 4, and  $y\psi$  must be of order 2. Moreover,  $y\psi$  cannot be in  $\langle x\psi \rangle$  because  $\psi$  is injective.

So we are reduced to 2 possible choices for  $y\psi$ , and 4 possible choices for  $x\psi$ . Because an automorphism is determined by its effect on generators, this gives us 8 possible automorphisms. Hence  $|\text{Aut } T| = 8$ . Lagrange's Theorem tells us that there are no non-trivial homomorphisms  $\psi : H \rightarrow \text{Aut } T$ .

**Case 3:**  $T \cong (C_2 \times C_2 \times C_2)$  i.e.  $G \cong (C_2 \times C_2 \times C_2) \rtimes C_3$

Somehow show  $\text{Aut } T \cong \text{GL}_3(2)$ . We can determine that  $|\text{GL}_3(2)| = 168 = 2^3 \cdot 3 \cdot 7$ , so  $\text{Aut } T$  has a Sylow 3-subgroup of order 3, isomorphic to  $C_3$ .

Theorem 2.11 tells us that all subgroups of order 3 are conjugate, so there is only one unique action (up to isomorphism) of  $H$  on  $T$ .

1 group —  $A_4 \times C_2$

**Case 4:**  $T \cong D_8$  i.e.  $G \cong D_8 \rtimes C_3$

If we say  $\langle s, r \mid s^2 = r^4 = 1, s^{-1}rs = r^{-1} \rangle = T$ , then consider two automorphisms,  $\varphi_s, \varphi_r \in \text{Aut } T$ , given by:

$$x\varphi_s = xs \quad \text{and} \quad x\varphi_r = xr \quad \text{for } x \in T$$

We see that  $\varphi_s$  has order 2, and  $\varphi_r$  has order 4. Additionally:

$$\varphi_s^{-1} = \varphi_s \quad \text{and} \quad \varphi_r^{-1} = \varphi_{r^{-1}}$$

Now consider:

$$x\varphi_s^{-1}\varphi_r\varphi_s = xs^{-1}rs = xr^{-1} = x\varphi_r^{-1}$$

Hence:

$$\text{Aut } T = \langle \varphi_s, \varphi_r \mid \varphi_s^2 = \varphi_r^4 = \iota, \varphi_s^{-1} \varphi_r \varphi_s = \varphi_r^{-1} \rangle \cong D_8$$

Lagrange's Theorem tells us that there are no non-trivial homomorphisms  $\psi : H \rightarrow \text{Aut } T$ .

**Case 5:**  $T \cong Q_8$  i.e.  $G \cong Q_8 \rtimes C_3$

1 group — binary tetrahedral

## 9 Groups of Order 30

Let  $G$  be a group of order  $30 = 2 \cdot 3 \cdot 5$ , and let  $n_3$  and  $n_5$  denote the number of Sylow 3-subgroups and Sylow 5-subgroups of  $G$  respectively. Then by Theorem 2.12:

$$n_3 = 1 \text{ or } 10 \quad \text{and} \quad n_5 = 1 \text{ or } 6$$

If  $n_3 = 10$ , then there are 20 elements of order 3, and if  $n_5 = 6$  then there are 24 elements of order 5 in  $G$ .  $G$  only has 30 elements, so then either:

$$n_3 = 1 \text{ and } n_5 = 6, \quad n_3 = 10 \text{ and } n_5 = 1 \quad \text{or} \quad n_3 = n_5 = 1$$

So if  $T$  is a Sylow 3-subgroup of  $G$  and  $F$  is a Sylow 5-subgroup, then at least one must be normal in  $G$ . So  $T \trianglelefteq G$  or  $F \trianglelefteq G$  or both.

Let  $H = TF$  and by Lagrange's Theorem,  $T \cap F = \mathbf{1}$ , hence  $|H| = 15$  by Lemma 2.18. We know from our classification of groups of order  $pq$  that  $H \cong C_{15}$ . Notice that a Sylow 2-subgroup  $K \leq G$  has order 2, so  $K \cong C_2$ . Let  $\langle t \rangle = K$  and  $\langle v \rangle = H$ . By the same argument as above,  $H \cap K = \mathbf{1}$  and  $|HK| = 30$ . Hence  $G = HK$ .

Because  $|H| = 15 = \frac{30}{2}$ , the index of  $H$  in  $G$  is 2, and we know a subgroup of index 2 is normal, so  $H \trianglelefteq G$ . Moreover,  $G = H \rtimes K$ .

By Lemma 2.8:

$$\text{Aut } C_{15} = (\mathbb{Z}/15\mathbb{Z})^\times \cong (\mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/5\mathbb{Z})^\times \cong (\mathbb{Z}/3\mathbb{Z})^\times \times (\mathbb{Z}/5\mathbb{Z})^\times \cong C_2 \times C_4$$

A homomorphism,  $\psi : C_2 \rightarrow C_2 \times C_4$  preserves element order and we know  $\psi$  is determined by its effect on a generator. So then  $t\psi$  has four possibilities: either the identity, or one of the three elements of order 2.

Additionally,  $\psi$  preserves the Sylow subgroups of  $H$ . So write  $H = \langle v^3 \rangle \times \langle v^5 \rangle$ , the direct product of its Sylow subgroups.

So the action of  $K$  on  $H$  is either trivial or by inversion on each of the Sylow subgroups of  $H$ , giving us 4 possibilities:

**Case 1:** Trivial action on both Sylow subgroups.

In this case, because the action is trivial on all of  $H$ , we recover the direct product,  $G = H \times K \cong C_{30}$ .

**Case 2:** Inversion on both Sylow subgroups.

Here,  $K$  acts on all of  $H$ , so we obtain:

$$G = \langle v, t \mid v^{15} = t^2 = 1, t^{-1}vt = v^{-1} \rangle$$

which we recognise as  $D_{30}$ .

**Case 3:** Inversion on  $\langle v^5 \rangle$ .

We know already, from our classification of groups of order  $2p$ , that  $C_3 \rtimes C_2 \cong D_6$ .

$$G = \langle v^3 \rangle \times (\langle v^5 \rangle \rtimes K) \cong C_5 \times D_6$$

So then because the action on  $\langle v^3 \rangle$  is trivial:

**Case 4:** Inversion on  $\langle v^3 \rangle$ .

Similar to above, we obtain:

$$G = \langle v^5 \rangle \times (\langle v^3 \rangle \rtimes K) \cong C_3 \times D_{10}$$

Hence any group of order 30 is isomorphic to one of:

$$C_{30}, \quad D_{15}, \quad C_5 \times D_6, \quad \text{or} \quad C_3 \times D_{10}$$
